Lecture 04: Succinct Planar Graphs and Range Min-Max Trees

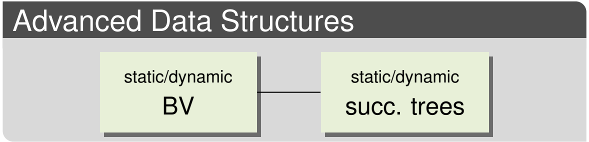
Florian Kurpicz

PINGO

https://pingo.scc.kit.edu/685523

Recap: Succinct (Dynamic) Graphs

- dynamic bit vector
- dynamic succinct trees
- which was the easiest representation for dynamic trees **PINGO**



Today's Plan

- preliminaries planar graph
- succinct planar graph representation
- range min-max trees
- project

Planar Graphs (1/2)

Definition: Planar Graph

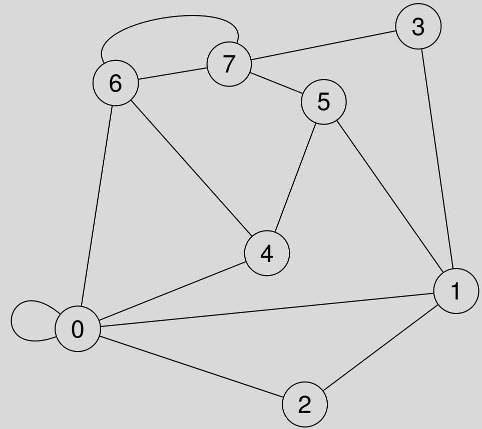
A graph $G = (V, E)$ is planar, if it

- can be drawn on the plane such that
- no edges cross each other

- drawing (planar) embedding of the graph
- not unique

a graph is planar if it has no minor

- $K_{3,3}$
- K_5

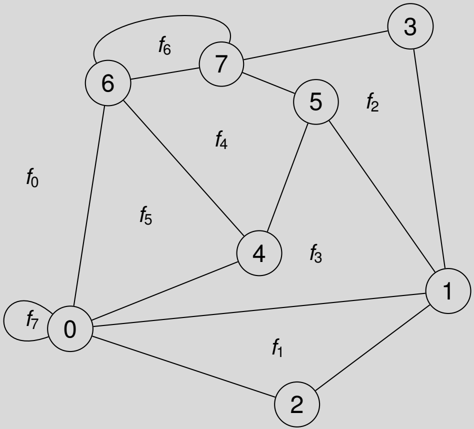


Planar Graphs (2/2)

- embedding is defined by order of neighbors
- this defines faces
- must specify outer face

Now Consider Only

- connected planar graphs with embedding,
- multi-edges, and
- self-loops ℹ appear twice in list of edges



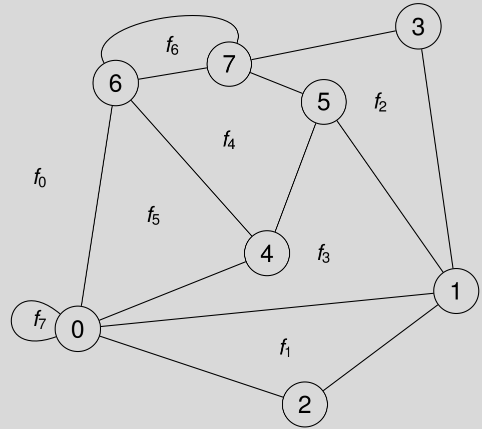
Dual Graph of Planar Graph

Definition: Dual Graph

Given an embedding of a planar graph G, the dual graph G^* of G has

- one node for each face of G and
- one edge e' for each edge e in G such that e' crosses e and is incident to the faces separated by e

- dual graph is unique for the embedding
- dual graph is planar

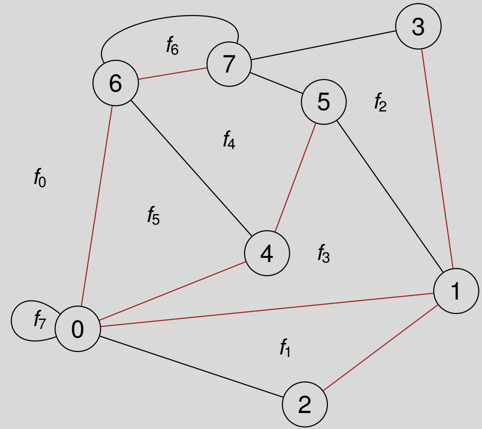


Spanning Trees

Definition: Spanning Tree

Given a connected graph $G = (V, E)$, a spanning tree is a tree $T = (V, E')$ with $E' \subseteq E$

- consider spanning tree of planar graph and
- its dual graph
- trees can be represented succinctly



Recap: Balanced Parentheses

Karlsruhe Institute of Technology

Definition: BP

Starting at the root, traverse the tree in depth-first order and append a

- left parenthesis if a node is visited the first time
- right parenthesis if a node is visited the last time

to the bit vector

```
 ab cd ef g   h ij k
(()(()(()()))()(()()))
```

- $excess(i) = rank_{``("}(i) - rank_{``)"}(i)$
- $fwd\_search(i, d) =$
  $\min\{j > i \colon excess(j) - excess(i-1) = d\}$
- $bwd\_search(i, d) =$
  $\max\{j < i \colon excess(i) - excess(j-1) = d\}$

- $findclose(i) = fwd\_search(i, 0)$
- $findopen(i) = bwd\_search(i, 0)$
- $enclose(i) = bwd\_search(i, 2)$

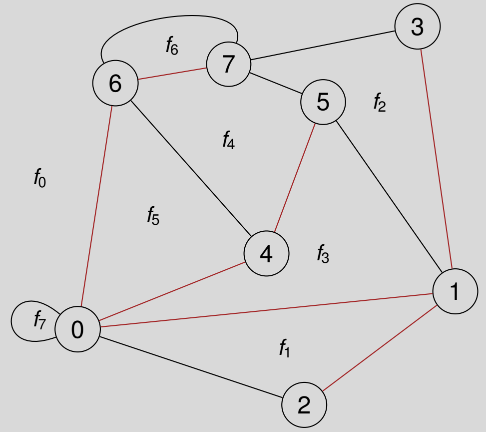
Succinct Planar Graph: General Idea [Fer+20; Tur84]

- given connected planar graph G and its dual G^*
- let T be spanning tree of G
- construct complementary spanning tree T^* of G^* using only edges not crossing edges in T

- edges are stored in adjacency lists

Definition: Incidence

Given a face f and a vertex v, an incidence of f in v is a pair of edges e, e', such that v is part of f and e, e' are incident of f and consecutive in the adjacency list of v



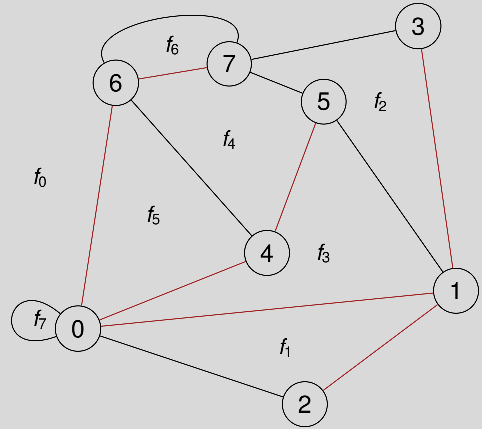
Traversal of the Graph gives Traversal of Trees (1/2)

Lemma: Graph-Tree-Traversal

Given an embedding of G, a spanning tree T of G, and its complementary spanning tree T^* of the dual of G. When

- traversing T depth-first, starting at any node on the outer face
- processing edges in counter-clockwise order
- (for the root choose an arbitrary incidence of the outer face),

each edge not in T corresponds to the next edge visited in a depth-first traversal of T^*



Traversal of the Graph gives Traversal of Trees (2/2)

Proof Graph-Tree-Traversal

- proof by induction
- correct in the beginning
- processed i edges, $(i+1)$-th edge is (v, w)
- if (v, w) is in T, nothing changes
- example on the board

Proof Graph-Tree-Traversal

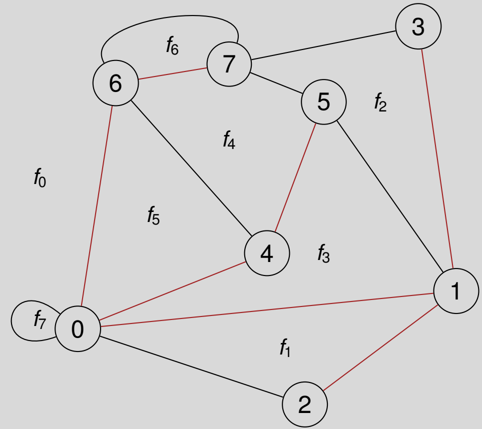
- proof by induction
- correct in the beginning
- processed i edges, $(i+1)$-th edge is (v, w)
- if (v, w) is in not T, then
- visit new edge in T'
- due to counter-clockwise visiting of nodes in G, going deeper in T^*
- example on the board

Succinct Planar Graph Representation

Succinct Graphs ($n = |V|$ and $m = |E|$)

- bit vector $A[0..2m)$ with $A[i] = 1 \iff$ the i-th edge processed is in T
- bit vector $B[0..2(n-1))$ with $B[i] = "("$ $\iff$ i-th time an edge in T is processed is the first time that edge is processed
- bit vector $B^*[0..2(m-n+1))$ with $B^*[i] = "("$ $\iff$ i-th time an edge not in T is processed is the first time that edge is processed

- $A =$ `0110110101110010110100010100`
- $B =$ `(()())(())(())`
- $B^* =$ `()((()(()))()()`



Simple Planar Succinct Graph Operations (1/2)

- $\mathit{first}(v)$ return i such that the first edge processed when visiting v is processed i-th during traversal
- $\mathit{next}(i)$ return j such that next edge that is processed when visiting v by i-th edge is processed j-th during traversal
- $\mathit{mate}(i)$ return j such that edge is processed i-th and j-th during traversal
- $\mathit{vertex}(i)$ return node v that is visited when processing i-th edge during traversal

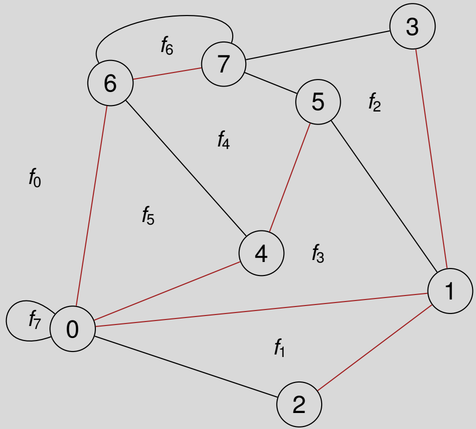
Simple Planar Succinct Graph Operations (2/2)

- all operations work in $O(1)$ time
- using rank and select queries on A
- using BP representation of T and T^*

- $A = \texttt{0110110101110010110100010100}$
- $B = \texttt{(()())(())(())}$
- $B^* = \texttt{()(()(()))()()}$

$\mathit{first}(0) = 0$	$\mathit{mate}(0) = 3$	$\mathit{vertex}(3) = 2$
$\mathit{next}(0) = 1$	$\mathit{mate}(1) = 9$	$\mathit{vertex}(9) = 1$
$\mathit{next}(1) = 10$	$\mathit{mate}(10) = 16$	$\mathit{vertex}(16) = 4$
$\mathit{next}(10) = 17$	$\mathit{mate}(17) = 25$	$\mathit{vertex}(25) = 6$

- example on the board



Getting the Degree

- while node has *next*
- increase counter and go to *next*
- return counter

- running time depends of degree of node
- better running time preferable

- speed up queries using $o(m)$ additional bits
- let $f(m) \in \omega(m)$
- mark in $D[0..m)$ nodes with degree $> f(m)$
  - at most $m/f(m)$ ones (sparse)
- for these nodes store degree unary in $E[0..2m)$
  - also sparse
- compressed sparse bit vectors require $o(m)$ space

- degree queries require only $O(f(m))$ time
- example on the board

Conclusion Succinct Planar Graphs

Karlsruhe Institute of Technology

Lemma: Succinct Planar Graphs

Storing an embedding of a connected planar graph with m edges requires $4m + o(m)$ bits and all nodes incident to a node can be iterated over in (counter-)clockwise order in constant time per edge. Finding the degree of a node can be done in $O(f(m))$ time for any function $f(m) \in \omega(1)$

Range Min-Max Trees (1/2)

Definition: Range Min-Max Tree

Given a bit vector B of length n and a block size b, store for each consecutive block (from s to e) of BV

- total excess in block: $\mathit{excess}(e) - \mathit{excess}(s-1)$
- minimum left-to-right excess in block: $\min\{\mathit{excess}(p) - \mathit{excess}(s-1) \colon p \in [s, e)\}$

and build a binary tree over these blocks, where each node stores the same total information for blocks in all its leaves

- example on the board

Lemma: Range Min-Max Tree Space

A range min-max tree with block size b for a bit vector of size n requires $n + O((n/b)\log n)$ bits of space

Range Min-Max Trees (2/2)

fwdsearch in a Range Min-Max Tree

- scan block
- if not found traverse tree
- identify block in tree
- scan block

- process c bits at a time
- first align with next c bits
- requires $O(c + b/c)$ time

- going up and down tree in $O(\log(n/b))$ time
- scanning last block requires $O(c + b/c)$ time

- by choosing $b = c \log n$ this requires
- $O(\log n)$ time and $n + O(n/(c \log n)) = n + o(n)$ bits space

Improvements

- two level approach
- build range min-max trees for chunks of size $\Theta(\log^3 n)$
- $O(\log \log n)$ query time inside a chunk
- can result in total query time of $O(\log \log n)$

Conclusion and Outlook

This Lecture

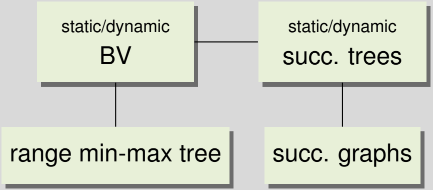
- succinct planar graphs
- range min-max trees

- **no live lecture next week**
- video only
- will start half an hour earlier on 30.05. for questions

Next Lecture

- predecessor data structures
- introduction to range minimum queries

Advanced Data Structures



Project

Karlsruhe Institute of Technology

- detailed information on the homepage
- implement dynamic bit vectors and BP
- deadline: 15.07.2022
- present results in 5 minutes on 25.07.2022
